

## Useful Info/Links for using Clusters.

A DX Cluster is a network of computers that collect and disseminate information about amateur radio DX (long-distance) contacts. These computers, called nodes, are linked together to form a larger network, or cluster. Users connect to these nodes to share information about DX spots, send messages, and access various other features.

### Cluster Commands

DX cluster commands allow users to interact with DX (long-distance) cluster networks, primarily used by amateur radio operators to share information about spotted stations and other DX-related data. Common commands include `SHOW/DX` to view recent spots, `SET/NAME` to set user information, and various filtering options to refine the displayed information.
